

D2. Encrypting Messages

time limit per test: 2 seconds

memory limit per test: 256 megabytes

input: standard input

output: standard output

The Smart Beaver from ABBYY invented a new message encryption method and now wants to check its performance. Checking it manually is long and tiresome, so he decided to ask the ABBYY Cup contestants for help.

A message is a sequence of n integers a_1, a_2, \dots, a_n . Encryption uses a key which is a sequence of m integers b_1, b_2, \dots, b_m ($m \leq n$). All numbers from the message and from the key belong to the interval from 0 to $c - 1$, inclusive, and all the calculations are performed modulo c .

Encryption is performed in $n - m + 1$ steps. On the first step we add to each number a_1, a_2, \dots, a_m a corresponding number b_1, b_2, \dots, b_m . On the second step we add to each number a_2, a_3, \dots, a_{m+1} (changed on the previous step) a corresponding number b_1, b_2, \dots, b_m . And so on: on step number i we add to each number $a_i, a_{i+1}, \dots, a_{i+m-1}$ a corresponding number b_1, b_2, \dots, b_m . The result of the encryption is the sequence a_1, a_2, \dots, a_n after $n - m + 1$ steps.

Help the Beaver to write a program that will encrypt messages in the described manner.

Input

The first input line contains three integers n , m and c , separated by single spaces.

The second input line contains n integers a_i ($0 \leq a_i < c$), separated by single spaces — the original message.

The third input line contains m integers b_i ($0 \leq b_i < c$), separated by single spaces — the encryption key.

The input limitations for getting 30 points are:

- $1 \leq m \leq n \leq 10^3$
- $1 \leq c \leq 10^3$

The input limitations for getting 100 points are:

- $1 \leq m \leq n \leq 10^5$
- $1 \leq c \leq 10^3$

Output

Print n space-separated integers — the result of encrypting the original message.

Examples

input	Copy
<pre>4 3 2 1 1 1 1 1 1 1</pre>	
output	Copy
<pre>0 1 1 0</pre>	

input	Copy
<pre> 3 1 5 1 2 3 4 </pre>	
output	Copy
<pre> 0 1 2 </pre>	

Note

In the first sample the encryption is performed in two steps: after the first step $a = (0, 0, 0, 1)$ (remember that the calculations are performed modulo 2), after the second step $a = (0, 1, 1, 0)$, and that is the answer.
